# Genomic selection

---

- › Using dense SNPset på predict breeding values
  - › Markers/haplotypes in close linkage disequilibrium with QTL
  - › Many "phenotypes" for each marker/haplotype to estimate effects accurately
- › Critical factors
  - › SNP density
  - › Size of reference population (and effective population size)
  - › Interplay between these factors in our breeds?

# Accuracy increase with reference size

---

# Improving genomic prediction by EuroGenomics collaboration

---

- › Exchange genotypes between VikingGenetics, CRV, UNCEIA, DHV-VIT
- › Increase reference from 4500 to 16.000
- › Three different SNPsets used
- › Initial imputation step to predict unobserved SNPs for CRV bulls

# Imputation using LD and LA information

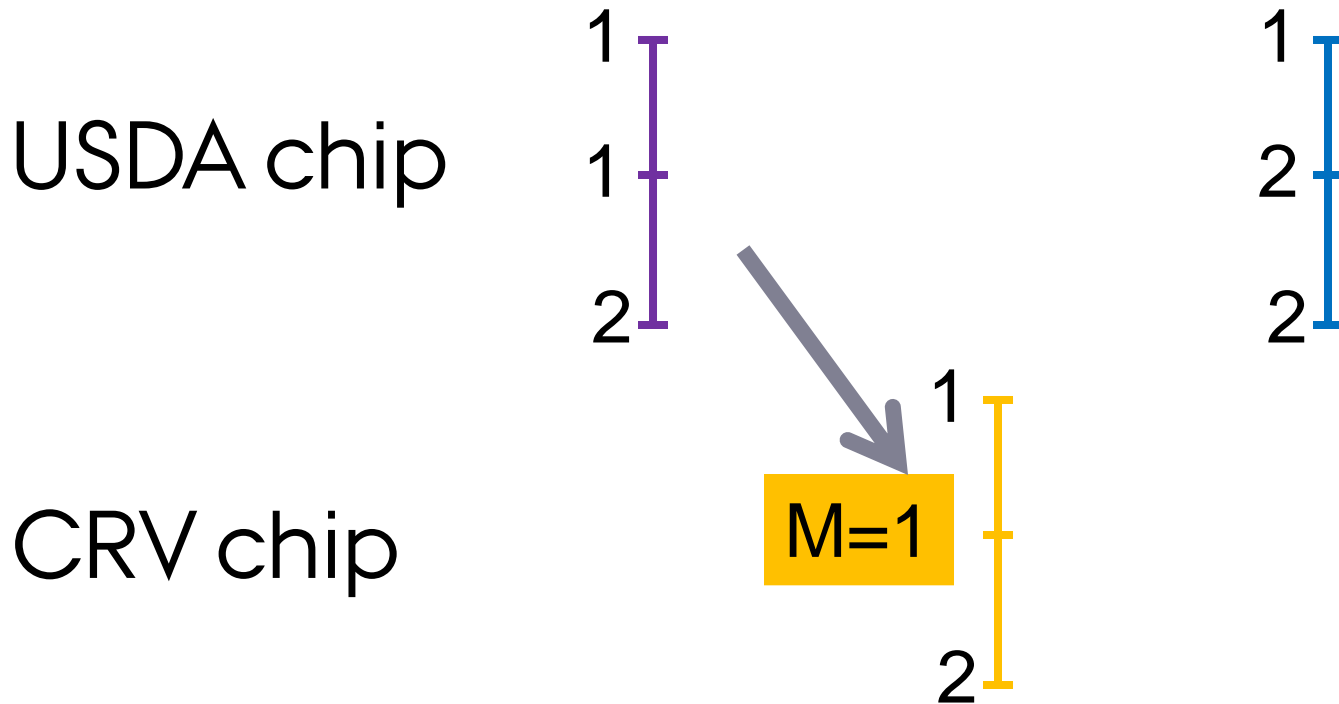

USDA chip

CRV chip

# Imputation using LD and LA information

AARHUS  
UNIVERSITY

# Imputation of USDA chip from CRV (Tom Druet)

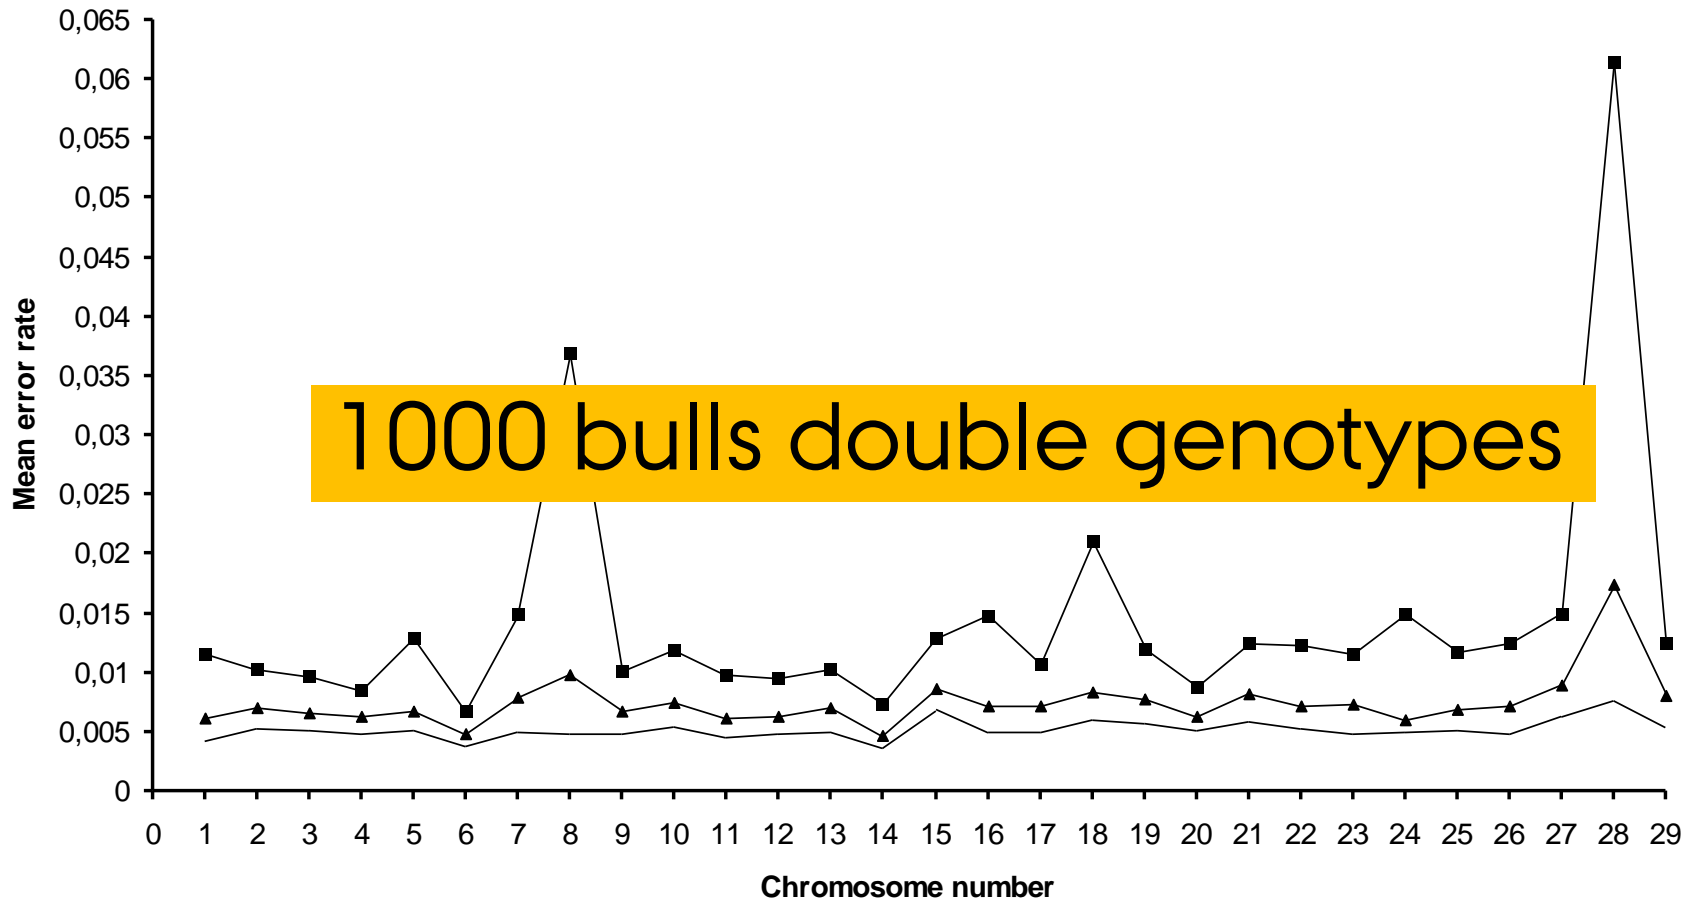

---

- › To study imputation (prediction of missing genotypes) across CRV 60K SNP panel and Illumina Bovine SNP50<sup>TM</sup> SNP chip («USDA» chip)

# Double genotyping 500, 1000, or 2000 bulls

---

# Improving genomic prediction by EuroGenomics collaboration

---

- › Objective: Increase reliabilities of genomic breeding values by combining reference populations
  
- › Hypothesis: Reliability increase 10-15% by using combined european reference compared to a purely Nordic reference

# Joint EuroGenomics dataset

---

- › 15,966 EuroGenomics bulls
- › 19.4 million daughters
- › 939 bulls with daughters in multiple countries
- › Median number of daughters were:
  - › DHV-VIT(117), UNCEIA (85), VikingGenetics (117), CRV (153)

# Reference and test population

---

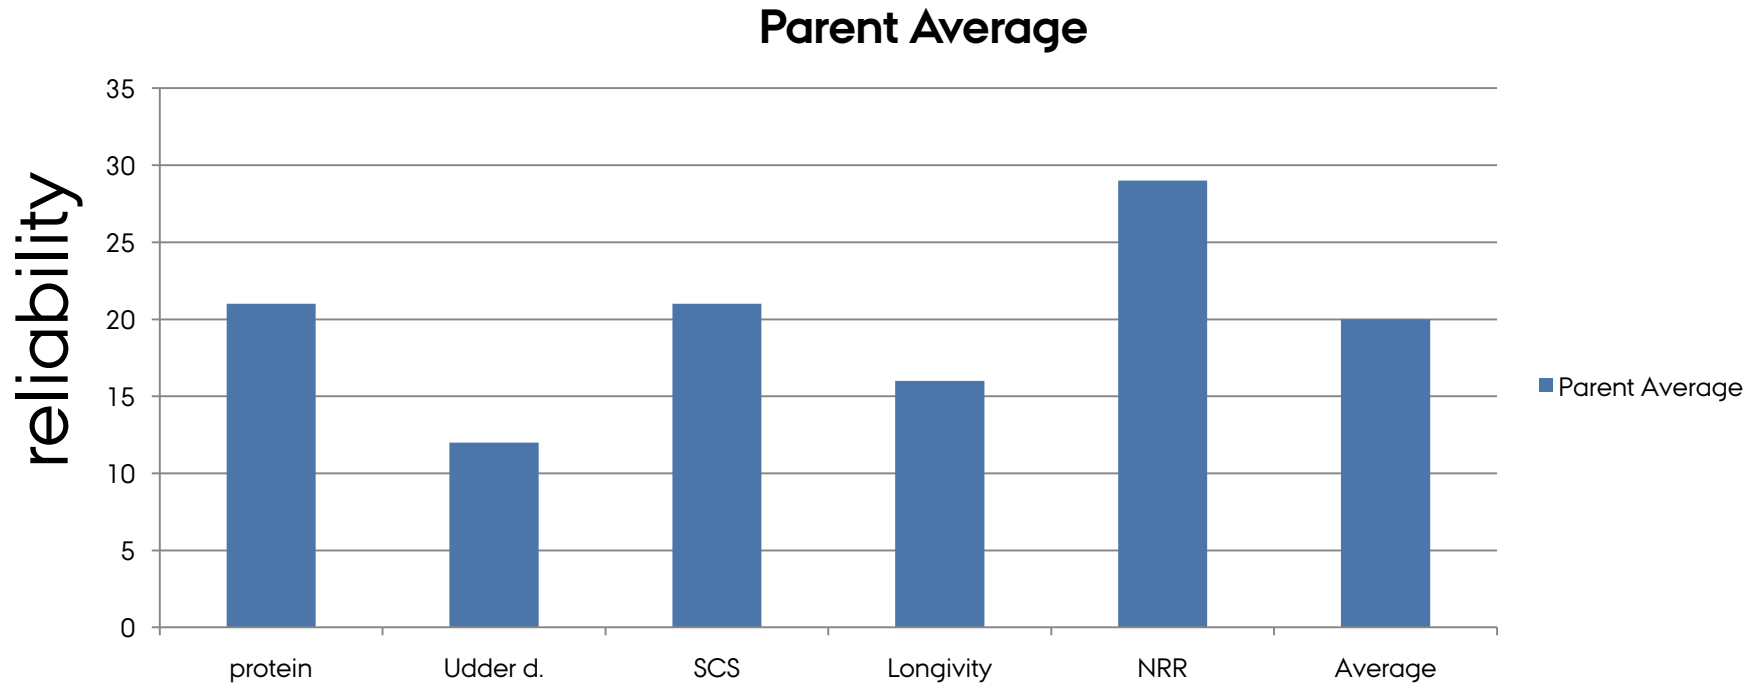

- › Nordic reference population
  - › 75% of domestic population (oldest bulls)
  
- › EuroGenomics reference population
  - › all bulls born before same date as for domestic
  
- › Test population
  - 25% youngest bulls
  - Sire in reference
  - EDC min. 20

# Data

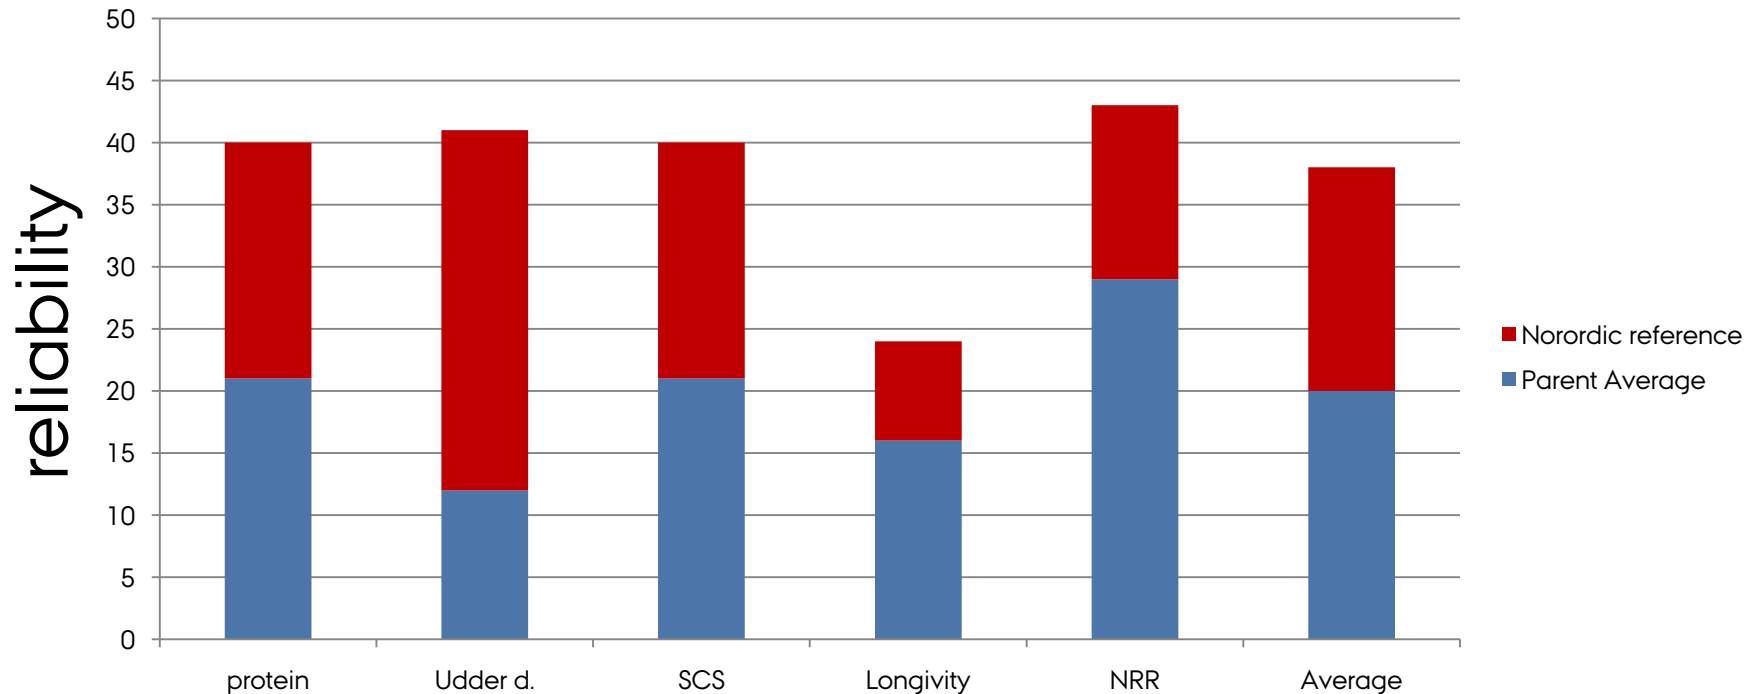

---

- SNP data
  - DSF, Fr, Deu: USDA Illumina 50K
  - Holland: Imputed from costum 50K Illumina chip
- Phenotypes
  - Deregressed proofs of Interbull jan. 2010 (domestic scale)
- Traits
  - protein, udder deapth, SCS, Longivity, NRR

# Reliability of parent average

# Reliability of GEBVs using Nordic reference

# Reliability of GEBVs using European reference

# Conclusions

---

- › Reliability increased by 11% (less than expected?)
- › Starting point higher than expected
- › Genetic correlation between traits less than 1 over the 4 countries

# What about the other breeds?

---

- › Jersey
- › Red Nordic breeds
  - › RDM
  - › SRB
  - › FAY

# Clustering of the red breeds?

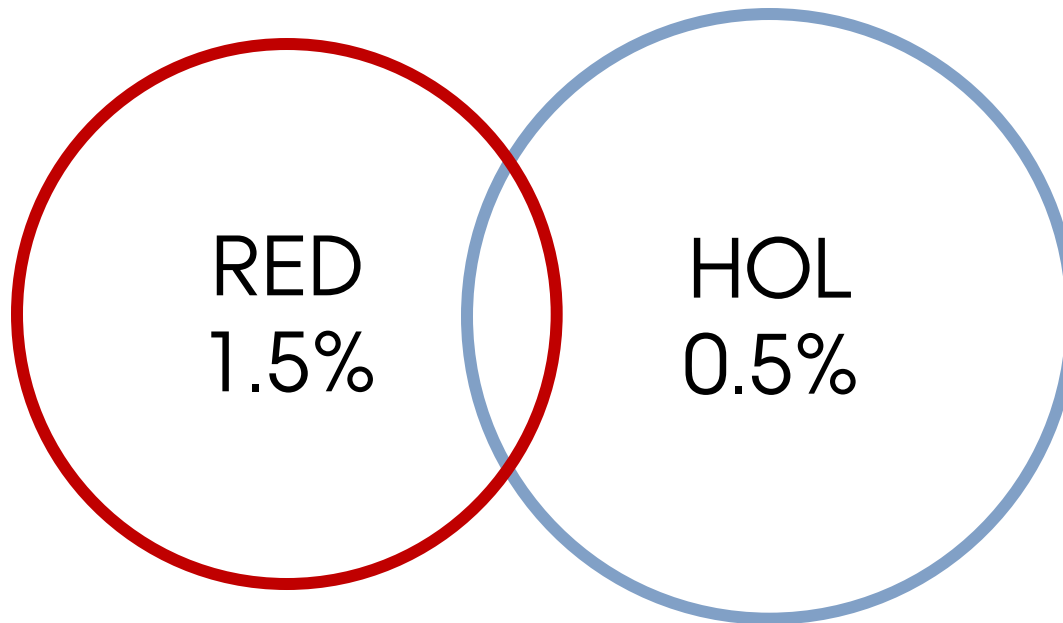

# Increase in accuracy by common reference (SLU, AU, MTT)

# Increase in accuracy by common reference with Holstein

---

## Reliability affected by:

- + More bulls with sire in reference
- + Better estimation of SNP effects
- Several (related) breeds
- Relationships within breed

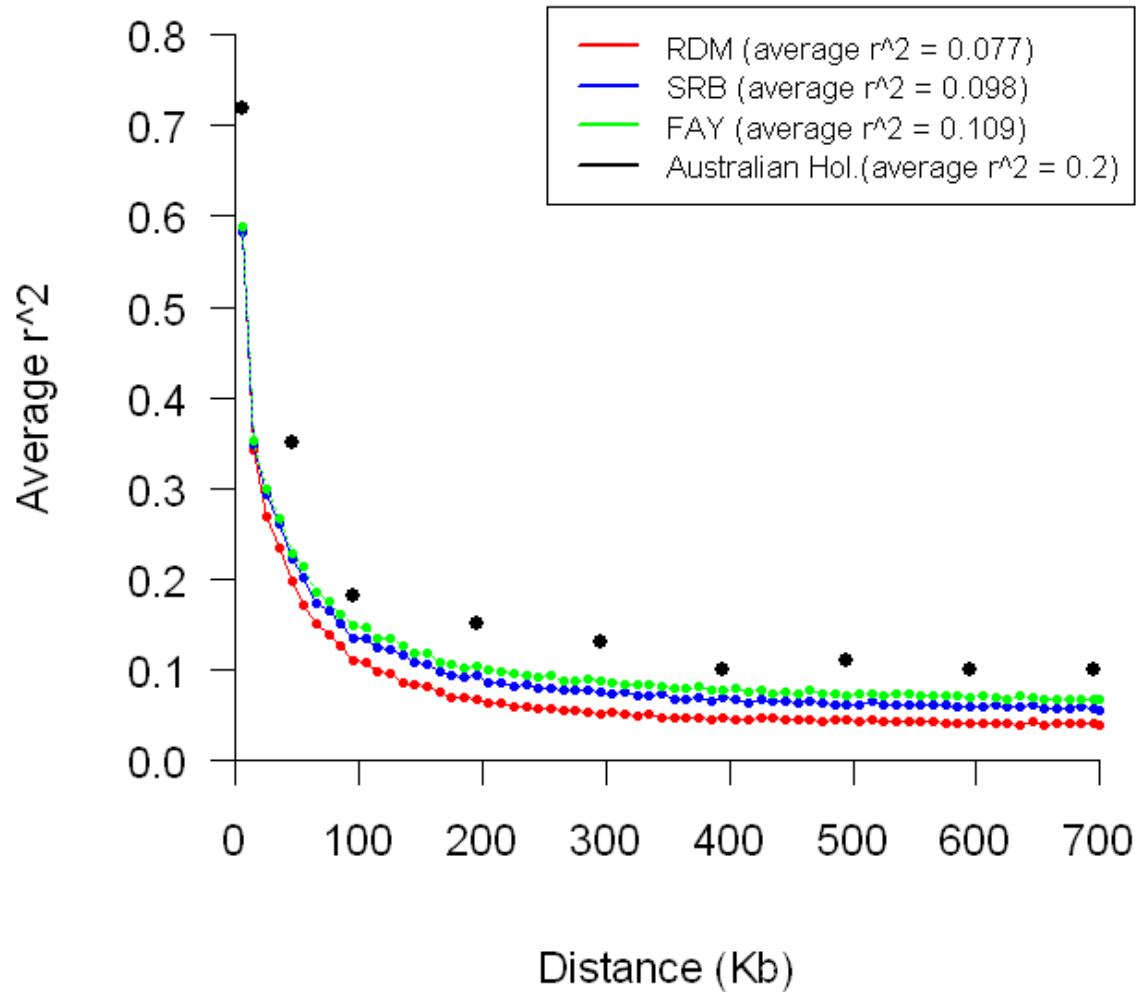

Some effects cancel out !

# Strength of Associations

# Strength of Associations

# “Direction” of Association Persistency of Phase

SNP Allele	Effect on Mastitis Resistance
1	++
2	--

# Persistency of Phase

# SNP Density and Associations

More crossing  
over possible for  
genes far apart

Fewer crossing over  
possible for genes  
close together

# Improvements with BovineHD

---

- › Distance between SNP and QTL becomes much shorter
  - › Stronger associations within breed  
(Marginal effect)
  - › Direction of association more similar across breed  
(Large effect, especially for RDM ⇔ SRB&FAY and HOL ⇔ RED)
- › Benefits greater when more data is added

# Imputation to Combine

- > <1% error rate for Bovine SNP50K & CRV50K
- > ~3% error rate for Bovine SNP50K & 3k
- ? Error rates for Nordic Red

# Available SNP-chips

---

## Illumina

- › Bovine SNP50K
- › Bovine HD
- › Bovine 3K panel
- › Customized chips (CRV)

} Subsets of  
each other

## Affymetrix

- › Bovine 25K SNP Kit

...more to come ...

# Upgrade SNP50K ⇒ BovineHD

- › Need to genotype some bulls in the reference population with BovineHD
  - › Only influential bulls
- › Holstein
  - › Reduce costs through EuroGenomics
    - › 500+500
- › Nordic Red
  - › Evaluate how much re-genotyping is needed
  - › Second half of 2010

# Opportunities with 3K

---

- › Large scale screening of potential bull dams
  - › Contract matings
  - › Embryo flushing
  
- › Cows comprise the future reference population ?!
  - › Tendency to reduce number of bulls

# New data sources and traits

---

## › Recording devices

- › Milk flow meters
- › Voluntary Milking systems
- › Activity meters
- › Herd navigator
- › ...

› Collect phenotypic data

› Genotype cows with 3K panel

} Genomic selection  
for new traits

# Summary

---

- › Reliability of GEBVs depend strongly on reference size
- › Large increase for HOL in EuroGenomics
- › Smaller increase for Nordic Red breeds
- › High density SNP set will be important
- › Low density SNP set for screening and reference
- › Imputation techniques are crucial
